## 1. Specific Heat Capacity (c)

Specific heat capacity is a measure of the heat energy needed to raise the temperature of a unit mass by one degrees Celsius (see data book).

Eg. $\mathrm{c}=4180 \mathrm{~J} / \mathrm{kg}^{0} \mathrm{C}$. for water $\rightarrow$ this means that every kg of water requires 4180J of energy to increase in temperature by $1^{\circ} \mathrm{C}$.

$$
E_{h}=c m \Delta T
$$

| Symbol | Name | Unit | Unit Symbol |
| :---: | :---: | :---: | :---: |
| $\mathrm{E}_{\mathrm{h}}$ | Energy | joules | J |
| c | Specific Heat Capacity | joules per kilogram degree Celsius | $\mathrm{J} / \mathrm{kg}^{\circ} \mathrm{C}$ |
| m | mass | kilograms | $\mathrm{kg}^{\circ}$ |
| $\Delta \mathrm{T}$ | Change in Temperature | degrees Celsius | ${ }^{\circ} \mathrm{C}$ |

1. 2 kg of water is placed in a fridge to cool it to $5^{\circ} \mathrm{C}$. When it was placed in the fridge it was $25^{\circ} \mathrm{C}$. How much heat energy is removed from the water?

$$
\begin{gathered}
\mathrm{E}_{\mathrm{h}}=\mathrm{cm} \Delta \mathrm{~T} \\
E_{h}=4180 \times 2 \times(25-5) \\
E_{h}=167200 \mathrm{~J} \\
E_{h}=1.67 \times 10^{5} \mathrm{~J}
\end{gathered}
$$

2. A 16 kg sample of metal requires 35.2 kJ to increase its temperature by $5^{\circ} \mathrm{C}$. What type of metal is it?

$$
\begin{gathered}
\mathrm{E}_{\mathrm{h}}=\mathrm{cm} \Delta \mathrm{~T} \\
35.2 \times 10^{3}=c \times 16 \times 5 \\
c=440 \mathrm{~J} / \mathrm{kg}^{\circ} \mathrm{C} \\
\text { The metal is iron }
\end{gathered}
$$

## -

## 2. Experiment

## Describe how the experiment below could be used to find the specific heat capacity

 of a material. Suggest improvements to your experiment.- The initial temperature of the block is measured on the thermometer.
- The heater is switched on from the power supply for 10 minutes.
- The final temperature is recorded from the thermometer.
- Using $\mathrm{P}=\mathrm{E} / \mathrm{t}$ calculate the energy provided by the heater to the block.
- Then use $\mathrm{E}_{\mathrm{h}}=\mathrm{cm} \Delta \mathrm{T}$, to calculate c .
*Remember to convert 10 mins $\rightarrow$ seconds ${ }^{*} \Delta \mathrm{~T}=$ final T - initial T

Improvements - insulating the metal block reducing heat loss to the surroundings (increasing final T) $\underline{\mathbf{O R}}$ Switch heater on for shorter time (decreasing final T)

## 3. Heat and Temperature

$\checkmark$ Heat is measured in joules and is a form of energy related to vibrations or total kinetic energy of particles in a substance.
$\checkmark$ Temperature is measured in Kelvin or degrees Celsius and is an indication of how hot or cold a substance is. So temperature is a measure of the average/mean kinetic energy.

4. Conservation of Energy Examples on next page

1. 1.5 kg of oil at $25^{\circ} \mathrm{C}$ is mixed with 3.0 kg of oil at $55^{\circ} \mathrm{C}$. Assuming no heat energy is lost to the surroundings, what is the final temperature of all the oil?

Using conservation of energy the increase in heat energy of the colder oll must be the same as the decrease in heat energy of the warm oil.

$$
\begin{aligned}
\Delta E_{1} & =\Delta E_{2} \\
\mathrm{~cm}_{1} \Delta \mathrm{~T}_{1} & =\mathrm{cm}_{2} \Delta \mathrm{~T}_{2} \\
\mathrm{~m}_{2} \Delta \mathrm{~T}_{1} & =\mathrm{m}_{2} \Delta \mathrm{~T}_{2} \\
1.5 \times \Delta \mathrm{T}_{1} & =3 \times \Delta \mathrm{T}_{2} \\
\Delta \mathrm{~T}_{1} & =2 \times \Delta \mathrm{T}_{2} \\
\text { Therefore } & \\
25+2 \Delta T_{2} & =55-\Delta \mathrm{T}_{2} \\
3 \Delta \mathrm{~T}_{2} & =30 \\
\Delta \mathrm{~T}_{2} & =10^{\circ} \mathrm{C}
\end{aligned}
$$

So the final temperature is $55-10=45^{\circ} \mathrm{C}$

The law of conservation of energy can be used with any type of energy, so it also allows us to investigate electrical appliances.
2. A kettle works on the UK mains ( $\mathbf{2 3 0} \mathrm{V}$ ) and a current of $\mathbf{1 2 ~ A}$ flows when it is switched on.
a) What is the power rating of the kettle?
b) How much energy would the kettle transform if it was switched on for 2 minutes?
c) What is the maximum mass of $20^{\circ} \mathrm{C}$ water which could be heated to $99{ }^{\circ} \mathrm{C}$ in this time?
d) What assumptions did you make in part $c$ ?
$\begin{array}{lrl}\text { c. } & \mathrm{E}_{\mathrm{n}}=\mathrm{cm} \Delta \mathrm{T} \\ \mathrm{T}_{1} & =20^{\circ} \mathrm{C} & 331 \times 10^{3}=4180 \times \mathrm{m} \times 79\end{array}$

$$
\begin{array}{rlrl}
\mathrm{T}_{1} & =20^{\circ} \mathrm{C} & 331 \times 10^{\circ} & =4180 \times \mathrm{m} \times 79 \\
\mathrm{~T}_{2} & =99{ }^{\circ} \mathrm{C} & \mathrm{~m} & =331 \times 10^{3} / 330220 \\
\Delta \mathrm{~T} & =\mathrm{T}_{2}-\mathrm{T}_{1}=79{ }^{\circ} \mathrm{C} & \mathrm{~m} & =1.002 \\
\mathrm{C} & =4180 \mathrm{~J} / \mathrm{kg}^{\circ} \mathrm{C} & \mathrm{~m} & =1 \mathrm{~kg}
\end{array}
$$

$$
\mathrm{E}_{\mathrm{h}}=331 \mathrm{~kJ}=331 \times 10^{3} \mathrm{~J}
$$

d. Assuming all energy supplied to kettle heats the water, none is lost to the surroundings.

$$
\begin{aligned}
& \text { a. } \quad \mathrm{V}=230 \mathrm{~V} \quad \mathrm{P}=\mathrm{IV} \\
& \mathrm{I}=12 \mathrm{~A} \quad \mathrm{P}=12 \times 230 \\
& \mathrm{P}=\text { ? } \\
& \mathrm{P}=2760 \mathrm{~W} \\
& \text { b. } P=2760 \mathrm{~W} \quad P=E / t \\
& t=2 \times 60=120 \mathrm{~s} \\
& 2760=E / 120 \\
& \mathrm{E}=\text { ? } \\
& E=120 \times 2760 \\
& \begin{array}{l}
\mathrm{E}=331200 \mathrm{~J} \\
\mathrm{E}=331 \mathrm{~kJ}
\end{array}
\end{aligned}
$$
